AUTHOR: Napalkov, N.V., Candidate of Agricultural Sciences

TITLE: February in Tataria (Fevral' v Tatarii)

PERIODICAL: Priroda, 1959, Nr 2, p 128 (USSR)

ABSTRACT: The author presents some principal data, partly based on data obtained from the Kazanskaya meteostantsiya (Kazan' Meteorological Station) on the weather and climate in the month of February in the Tataria. The mean temperature in Kazan' in February is minus 13.1°C . In 1957 it was minus 6.6°C and in 1941 minus 30°C with instances down to -45 and -50°C . Similar fluctuations were observed with respect to the precipitation. In 1955 the total precipitation in February was 80 mm or 38% of the average total, while in 1952 it was 2 mm or 9% of the average. The mean snow cover at the end of February is 1 to 1.2 m thick in the forests and 30 cm on the open fields. The difference in thickness is due to the strong winds that sweep the open areas and accumulate the snow masses in depressions and ravines. Consequently the

Card 1/2

February in the Tatar

SOV/26-59-2-53/53

ground may freeze to a depth of 90 cm in open areas and to 30 to 40 cm in the forests with spruce and pine trees being the characteristic trees of these forests. The over-all weather picture for the month of February in the **Tataria** is characterized by an alternate sequence of spells of severe frost and snowstorms. Towards the end of the month the frost periods cease gradually.

AUTHOR: Napalkov, Yu. V.

TITLE: Seismic pickup grouping theory

SOURCE: Prikladnaya geofizika (sbornik statey), no. 27, 1960, 12-34

TEXT: The author disputes F. M. Gol'tsman's introduction of a "cutoff" frequency in the frequency characteristics of continuous groupings of seismic pickups when the latter are converted to discrete groupings, and attempts to discuss the sensitivity distribution functions and directivity patterns of discrete groupings without reference to frequency or time limitations placed on the functions. Using the delay theorem, he derives the directivity pattern directly for a discrete grouping having an arbitrary sensitivity distribution; the curve obtained represents a function of a generalized argument. The sensitivity distribution for a discrete grouping having a given directivity pattern is determined from Fourier series coefficients obtained by the least squares method. If the Fourier series is not infinite, the accuracy with which the given pattern

chromizing is done in a solid charge (a mixture of chromium powder with a part of the base metal), the electrical circuit and V.D.U. The chromium powder contains a small amount of the metal to be chromized. This is usually chrome, but can also be nickel or cobalt. The powder is packed into a mold and heated to a temperature of about 1000° F. The powder and chromized part will then be cooled and the mold removed. After cooling, the part will be cleaned and the excess powder removed.

After the part has been cleaned, it is placed in a bath of molten zinc which is held at a temperature of 800° F. The part is then lowered into the bath and allowed to remain for a period of time. The time will depend on the thickness of the part and the desired thickness of the coating.

TOPIC TAGS: iron powder, chromium coated powder, powder coating, chromium steel, steel powder iron alloy, chromium containing alloy, alloy powder

ABSTRACT: Experiments have been conducted to obtain iron powder with a predetermined, uniform distribution, chromium content of 10-12% by weight. The following methods were used: 1) the method of flame spraying; 2) the method of flame atomization; 3) the method of flame atomization with simultaneous addition of a solution of a reducing agent. The experiments show well that the method of flame atomization with simultaneous addition of a reducing agent is the most effective. The method of flame atomization with simultaneous addition of a reducing agent is the most effective. The method of flame atomization with simultaneous addition of a reducing agent is the most effective.

amount of loosening agent was 25 wt%, whereupon a sponge with a chromium content of 12.8% was obtained. Increasing the content of loosening agent to 30 wt% will increase chromium content to about 15 wt%. Conversely, With a higher content, a friable porous sponge containing residue of the chromizing mixture was formed. At a constant thickness of the iron powder layer, the chromium content of the resulting iron powder decreased with increasing amount of chromizing agent. The effect of chromizing agent on the chromium content of the resulting iron powder is shown in the table. For example, chromizing in a mixture containing 1.6% Cr powder at 1000°C, 1050°C, 1100°C, and 1373K yielded iron powders with a chromium content of 14.0, 13.4, 12.4, and 11.4, respectively. Chromizing; a mixture containing 1.6% Cr powder at 1000°C, yielded the best results. The use of such mixtures and combination of various chromizing temperatures, experimental conditions, and amounts of loosening agent provide the possibility to obtain various chromium contents in the chromized iron powder. TITLE: Investigation of conditions for producing chrome-alloyed iron powder by diffusion saturation from solid chromium-containing charges (report 2)

SOURCE: Poroshkovaya metallurgiya, no. 7, 1966, 10-14

TOPIC TAGS: iron powder, chromium containing alloy, powder metal production

ABSTRACT: This paper is a continuation of a study on the use of diffusion saturation for producing uniformly alloyed iron-chromium powders. The authors consider the effect which charge composition and alloying temperature have on chromium concentration in the powder particles. Charges containing 5, 10, 20, 30, 40 and 50% chromium powder were used for alloying iron powder at temperatures of 1073, 1173, 1273, 1373 and 1473°K. Holding time in all tests was 4 hours and the volumetric ratio of alloying powder to iron powder was held constant with a definite concentration of scarifier in the powder. The results are tabulated and graphed. An analysis of these data shows that iron-chromium powders with a wide range of compositions may be produced at a tempera-

Card 1/2

L 46005-66

ACC NR: AP6025932

ture of 1373°K using charges containing 5-50% chromium. However, since a denser sponge is produced at this temperature it is preferable in some cases to use lower alloying temperatures, particularly for producing powders with a low chromium concentration. Alloying at 1473°K is not recommended since the sponge is extremely dense and nonhomogeneous. Orig. art. has: 4 figures, 1 table.

TITLE: Fifth Ukrainian Scientific Technical Conference on Powder Metallurgy

SOURCE: Poroshkovaya metallurgiya, no. 8, 1966, 106

18 III

TOPIC TAGS: powder metallurgy, powder metal, sintered material, iron powder, sintering, powder metal sintering

ABSTRACT: The Fifth Ukrainian Scientific Technical Conference on Powder Metallurgy was held 29—31 March 1966 in Kiev. The conference was organized by the Institute for Problems in the Science of Materials jointly with the local administrations of the scientific and technical societies for toolmaking and machine building. The 180 participants representing 56 organizations and research institutes of the Ukrainian SSR and other Soviet republics heard a total of 35 reports and communications. The principal topics of the papers included The State-of-the-Art of Powder Metallurgy in the USSR and Abroad presented by I. M. Fedorchenco, Academician (AN UkrSSR); Improvements in Production Technology of Iron Powder

Card 1/2

L 01925-67

by Reduction, by L. A. Zhukovskaya (Kiev Plant of Powder Metallurgy) and A. N. Ostrika (Dneprovsk Aluminum Plant); Manufacture of Friction Type Sintered Products, by N. V. Kolpakov (Balashikha Machinebuilding Plant); High-Frequency Sintering of Powder Metal Construction Parts, by L. G. Yerchenko (NIITAVTOPROM); and Developments in the Manufacture of Parts from Refractory Materials, by I. A. Koshkin (Kiev Powder Metallurgy Plant). Other papers dealt with the production technology of porous sintered materials, properties of porous sintered titanium, antifriction properties of metal-plastics, obtaining porous materials from refractory compounds, chemical and heat treatment of sintered materials, and deposition of protective and ornamental coatings. The conference adopted resolutions concerning prospective research by institutes, laboratories and related organization for 1966—1970. Production technology, quality control, cost reduction, new sources of raw materials for metal powders and improvement of the nomenclature for sintered products at specialized plants were discussed in detail.

TOPIC TAGS: thermal conductivity, heat transfer, boundary value problem, contact boundary

ABSTRACT: The problem of heat transfer between B_1 and B_2 is considered. (B_2 is a medium filling a three-dimensional space with the exception of a medium B_1 which is bounded by a closed Lyapunov surface S .) A function $u(P, t)$ is sought, satisfying the following conditions:

$$1^o. \frac{\partial^2 u(P, t)}{\partial x^2} + \frac{\partial^2 u(P, t)}{\partial y^2} + \frac{\partial^2 u(P, t)}{\partial z^2} = \frac{1}{a_1^2} \frac{\partial u(P, t)}{\partial t}, P \in B_1, t > 0;$$

$$2^o. \frac{\partial^2 u(P, t)}{\partial x^2} + \frac{\partial^2 u(P, t)}{\partial y^2} + \frac{\partial^2 u(P, t)}{\partial z^2} = \frac{1}{a_1^2} \frac{\partial u(P, t)}{\partial t}, P \in B_2, t > 0;$$

$$3^o. [u(P, t)]_1 - [u(P, t)]_2 = g_1(P, t), \quad P \in S, t > 0;$$
